AMORPHOUS SOLID MODIFICATION OF BIS(2,4-DICUMYLPHENYL) PENTAERYTHRITOL DIPHOSPHITE

The present invention pertains to an amorphous solid modification of bis(2,4-dicumylphenyl)-pentaerythritol diphosphite, to a process for preparing said modification and the use thereof for stabilizing organic materials against oxidative, thermal or light-induced degradation.

Bis(2,4-dicumylphenyl)pentaerythritol diphosphite is a compound having the formula I

This compound of the formula I is useful as a processing stabilizer for organic materials as taught for example in U.S. Patent 5,364,895; U.S. Patent 5,438,086; US-A-2001/0023270; or US-A-2002/0040081. The compound of the formula I is disclosed as being a crystalline product melting at 230 – 232°C [U.S. Patent 5,438,086, Example 3, column 16, line 14]. The relatively high melting point of the crystalline product form of the compound of the formula I is a problem when stabilizing organic polymers processed at relatively low temperatures such as blow molding of HDPE and processing of natural rubber. The result is that the additive is not uniformly distributed within the organic polymer causing problems in the stabilization performance of the additive stabilizer.

In accordance with the present invention an amorphous form of the compound of formula I is obtained which does not suffer the problems associated with the higher melting product reported previously. This new amorphous form is characterized by a glass transition temperature (T_g) within the range of from 59 – 63°C and by an X-ray diffraction pattern which is featureless.

The instant invention also relates to a process for the preparation of the amorphous solid form of bis(2,4-dicumylphenyl)pentaerythritol diphosphite of the formula I, which comprises melting said compound and rapidly cooling the melt.

The preferred method consists of pouring, preferably dropping, the molten material onto a cool surface maintained below 30°C, more preferably near 20°C. Preferably, the cool surface is a metal surface, for example a metal surface present in a Sandvik Rotoformer®. The molten material can also be sprayed, preferably via nozzles, with a cooled gas onto a cool surface to form amorphous spherical granules. The temperature of the cooled gas is preferably below 30°C. Preferably, a melt distribution device is used to form uniform pellets if form giving is achieved from the melt. The amorphous solid thus obtained may be further ground or granulated into any desired particle size by conventional means.

The instant invention relates also to the amorphous solid form of bis(2,4-dicumylphenyl)penterythritol diphosphite, characterized by melting in the range of from 59 – 63°C and by an X-ray diffraction pattern which is featureless, obtainable by melting said compound and rapidly cooling the melt.

The amorphous solid according to the invention is highly suitable for stabilizing organic materials against oxidative, thermal or light-induced degradation.

Polymers of monoolefins and diolefins, for example polypropylene, polyisobutylene, polybut-1-ene, poly-4-methylpent-1-ene, polyvinylcyclohexane, polyisoprene or polybutadiene, as well as polymers of cycloolefins, for instance of cyclopentene or norbornene, polyethylene (which optionally can be crosslinked), for example high density polyethylene (HDPE), high density and high molecular weight polyethylene (HDPE-HMW), high density and ultrahigh molecular weight polyethylene (HDPE-UHMW), medium density polyethylene (MDPE), low density polyethylene (LDPE), linear low density polyethylene (LLDPE), (VLDPE) and (ULDPE).

Polyolefins, i.e. the polymers of monoolefins exemplified in the preceding paragraph, preferably polyethylene and polypropylene, can be prepared by different, and especially by the following, methods:

- a) radical polymerisation (normally under high pressure and at elevated temperature).

- b) catalytic polymerisation using a catalyst that normally contains one or more than one metal of groups IVb, Vb, VIb or VIII of the Periodic Table. These metals usually have one or more than one ligand, typically oxides, halides, alcoholates, esters, ethers, amines, alkyls, alkenyls and/or aryls that may be either π - or σ -coordinated. These metal complexes may be in the free form or fixed on substrates, typically on activated magnesium chloride, titanium(III) chloride, alumina or silicon oxide. These catalysts may be soluble or insoluble in the polymerisation medium. The catalysts can be used by themselves in the polymerisation or further activators may be used, typically metal alkyls, metal hydrides, metal alkyl halides, metal alkyl oxides or metal alkyloxanes, said metals being elements of groups Ia, IIa and/or IIIa of the Periodic Table. The activators may be modified conveniently with further ester, ether, amine or silyl ether groups. These catalyst systems are usually termed Phillips, Standard Oil Indiana, Ziegler (-Natta), TNZ (DuPont), metallocene or single site catalysts (SSC).

Further preferred compositions comprise, in addition to components (a) and (b) further additives, in particular phenolic antioxidants, light stabilizers and/or processing stabilizers.

Incorporation of the amorphous solid form of bis(2,4-dicumylphenyl)pentaerythritol diphosphate and, if desired, further additives in the polymeric organic material is carried out by known methods, for example before or during moulding or by applying the dissolved or dispersed compounds to the polymeric organic material, if appropriate with subsequent slow evaporation of the solvent. The amorphous solid modification according to the invention can also be added to the materials to be stabilized in the form of a masterbatch containing them, for example, in a concentration of 2.5 to 25% by weight.

The amorphous solid modification according to the invention can also be added before or during polymerization or before crosslinking.

The amorphous solid modification according to the invention can be incorporated into the material to be stabilized in pure form or encapsulated in waxes, oils or polymers.

The amorphous solid modification according to the invention can also be sprayed onto the polymer to be stabilized. It is capable of diluting other additives (for example the above-mentioned customary additives) or their melts, thus enabling them to be sprayed onto the polymer to be stabilized also together with these additives. Addition by spraying during deactivation of the polymerization catalysts is particularly advantageous, it being possible, for example, for the steam used for deactivation to be used for spraying.

In the case of bead polymerized polyolefins, it may be advantageous, for example, to apply the amorphous solid modification according to the invention, if desired together with other additives, by spraying.

The materials thus stabilized can be used in a wide range of forms, for example films, fibers, tapes, moulding compositions, profiles or as binders for paints, adhesives or cements.

As already mentioned, the organic materials to be protected are preferably organic, in particular synthetic, polymers. Of these, the materials being protected are particularly advantageously thermoplastic materials, in particular polyolefins. The excellent efficiency of the amorphous solid form of bis(2,4-dicumylphenyl)pentaerythritol diphosphite as processing stabilizer (thermal stabilizer) should be mentioned in particular. To this end, it is advantageously added to the polymer before or during its processing. It is however also possible to stabilize other polymers, for example elastomers, lubricants or hydraulic fluids against degradation, for example light-induced or thermal-oxidative degradation. For elastomers, see the above list of possible organic materials.

Suitable lubricants and hydraulic fluids are based, for example, on mineral or synthetic oils or mixtures thereof. Lubricants are known to one skilled in the art and described in the relevant technical literature, for example in Dieter Klamann, "Schmierstoffe und verwandte Produkte" (Verlag Chemie, Weinheim 1982), in Schewe-Kobek, "Das Schmiermittel-Taschenbuch" (Dr. Alfred Hüthig-Verlag, Heidelberg, 1974) and in "Ullmanns Enzyklopädie der technischen Chemie" vol. 13, pages 85 – 94 (Verlag Chemie, Weinheim, 1977).

Accordingly, a preferred embodiment of the present invention is the use of the amorphous solid form of bis(2,4-dicumylphenyl)pentaerythritol diphosphite as stabilizer for organic materials against oxidative, thermal or light-induced degradation.

The amorphous solid modification according to the invention is preferably used as processing stabilizer (thermal stabilizer) of thermoplastic polymers.

The present invention also provides a process for stabilizing an organic material against oxidative, thermal or light-induced degradation, which comprises incorporating therein or applying thereto the amorphous solid form of bis(2,4-dicumylphenyl)pentaerythritol diphosphite.

The instant amorphous solid form of bis(2,4-dicumylphenyl)pentaerythritol diphosphite shows a faster rate of dissolving and better solubility in organic materials, such as in polymers and in lubricants, as compared to the prior art crystalline form. This provides better

compatibility and more uniform distribution of the instant amorphous solid form of bis(2,4-dicumylphenyl)pentaerythritol diphosphite with an organic polymer during formulation compared to the prior art compound melting at 230 – 232°C.

Differential scanning calorimetry (DSC) measurements are obtained on a Mettler DSC 820 with aligned aluminum pan and temperature scan at +10°C per minute till 300°C.

X-ray diffraction patterns are recorded on a Philips Norelco X-ray Diffractometer unit, using Cu-K α radiation with a nickel filter.

The following Examples illustrate the invention further. Parts or percentages relate to weight.

Example 1: Preparation of the amorphous solid form of bis(2,4-dicumylphenyl)pentaerythritol diphosphite.

The compound of the formula I, bis(2,4-dicumylphenyl)pentaerythritol diphosphite, is prepared according to procedure of Example 3 of U.S. Patent 5,438,086. The crystalline compound with a melting point 230 – 232°C is heated to 250°C until a clear melt is obtained. The melt is cooled rapidly by pouring the molten material onto a cool surface maintained at 20°C to yield an amorphous solid with a T_g (DSC) of 61°C (measured at a standard heating rate of +10°C per minute). The clear transparent solid is conveniently ground into a white powder using a mortar and pestle. The X-ray diffraction pattern obtained using Cu-K α is featureless.

The melt is cooled rapidly by pouring the molten material onto a cool surface maintained at 20°C to yield an amorphous 1 : 1 blend with a T_g (DSC) of 53 - 55°C (measured at a standard heating rate of +10°C per minute).

Example 6: Preparation of the amorphous blend (6 : 1 : 3) of bis(2,4-dicumylphenyl)pentaerythritol diphosphite, Irganox HP 136[®] and Irganox 1010[®].

phenyl)propionate]; Ciba Specialty Chemicals Inc.) is heated to 250°C until a clear melt is obtained. The melt is cooled rapidly by pouring the molten material onto a cool surface maintained at 20°C to yield an amorphous 6 : 1 : 3 blend with a T_g (DSC) of 50°C (measured at a standard heating rate of +10°C per minute).

Example 7: Stabilization of multiple-extruded polypropylene homopolymer.

3 kg of a polypropylene homopolymer (PH 350) is dry-blended with 0.05 % calcium stearate and the additives according to Table 1. This blend is then extruded in a twin-screw extruder of Berstorff (RTM) (ZSK 25, L/D=46) at temperatures of at most 240°C. The extrudate is cooled by drawing it through a water bath and then granulated. This granulate is repeatedly extruded. After 3 extrusions, the melt flow index (MFI) and Yellowness Index (YI) is measured.

The change of the molecular weight is reported in terms of the melt flow index (MFI) according to the ASTM-D-1238-70, measured in a Göttfert melt flow indexer and loads as given below. Experiment errors of the MFI measurements are found to be ± 0.03 for the MFI measured at 190°C and 2.16 kg load, ± 0.06 for the MFI measured at 190°C and 5 kg load and ± 0.1 for the MFI measured at 190°C and 10 kg load. A substantial decrease in the melt index denotes poor stabilization. The color quality is reported in terms of Yellowness Index (YI) determined on the granules in accordance with the ASTM 1926-70 Yellowness Test. Low YI values denote little discoloration, high YI values severe discoloration of the samples. The results are summarized in Table 1.

Table 1:

Example	Additive	YI after 1 extr.	YI after 3 extr.	MFI after 1 extr.	MFI after 3 extr.
Example 7a ^{a)}	0.050 % Irganox 1010 ^(®) 0.025 % Irgafos 168 ^(®) 0.025 % Doverphos S 9228T ^(®)	-1.16	2.01	3.67	5.83
